

A close-up photograph of a timber joint. The image shows several layers of light-colored wood. A metal screw is visible, securing the top layer. Below the top layer, there is a layer of wood, followed by a layer of a bright orange resilient profile. The profile is rectangular and appears to be made of a soft material, possibly foam or rubber, designed to provide acoustic insulation and resilience. The wood grain is clearly visible throughout the structure.

RESEARCH & DEVELOPMENT

STRUCTURAL DESIGN AND ACOUSTICS

The mechanical behaviour of timber-to-timber shear connections with a resilient sound insulation profile in between was studied in depth, both in terms of strength and stiffness, through an extensive experimental campaign.

EXPERIMENTAL INVESTIGATION

1 ANALYTICAL CHARACTERISATION OF A GAP CONNECTION USING PREDICTIVE MODELS

For the analytical evaluation of the mechanical parameters of the connection (strength and stiffness), models available in the literature were applied, which modify Johansen's basic theory.

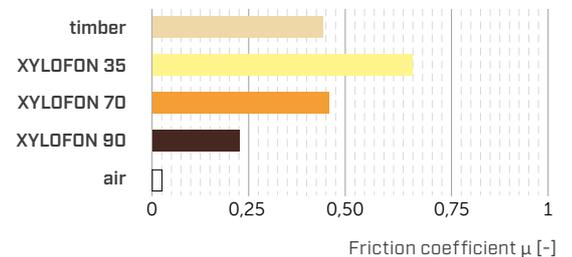

2 APPLICATION OF THE MODEL TO CONNECTIONS WITH AN INTERPOSED RESILIENT PROFILE

Over 50 configurations considered by varying numerous parameters.

RESILIENT PROFILES			CONNECTORS
Thickness investigated: 6 mm, 2 x 6 mm, 3 x 6 mm			
			
XYLOFON 35-50-70-80-90	PIANO A-B	PIANO C-D-E	HBS Ø6 HBS Ø8 HBS Ø10
Polyurethane (monolithic and deformable)	EPDM (expanded and compressible)	EPDM (monolithic and deformable)	

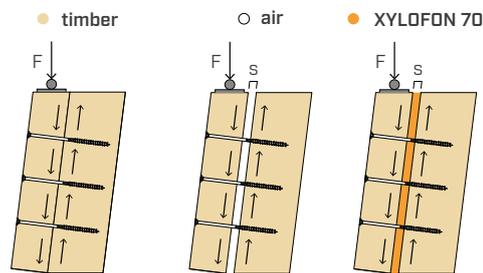

3 ASSESSMENT OF THE FRICTION COEFFICIENT μ FOR XYLOFON ACOUSTIC PROFILES

The tests carried out revealed interface properties of a frictional nature that seem to particularly influence the behaviour of the timber connections, especially in terms of strength.

4 EXECUTION OF MONOTONIC TESTS

For the validation of the predictive model studied, samples with one and two shear planes were tested.

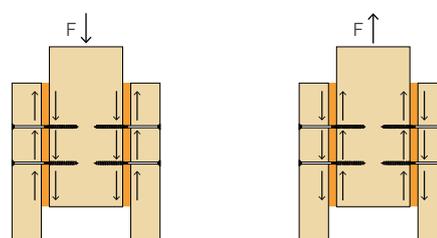

5 EXECUTION OF CYCLIC TESTS

For the comparison of the behaviour under monotonic and cyclic loads, samples with two shear planes were tested.

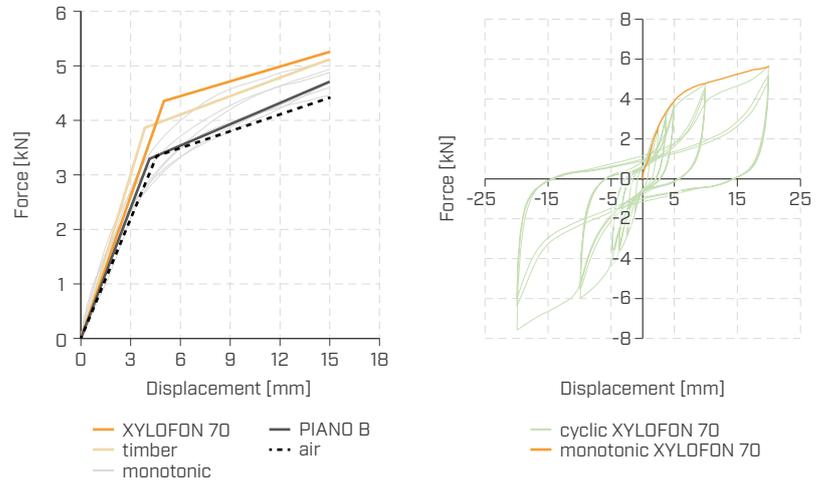

over 250 TESTS

Experimental campaign carried out in cooperation with:
CIRI Edilizia e Costruzioni
Interdepartmental Centre for Industrial Research
Alma Mater Studiorum - Università di Bologna

6 CAMPAIGN RESULTS

The results were analysed by bi-linearising the experimental curves. It can be seen that the cyclic behaviour is consistent with the monotonic behaviour.

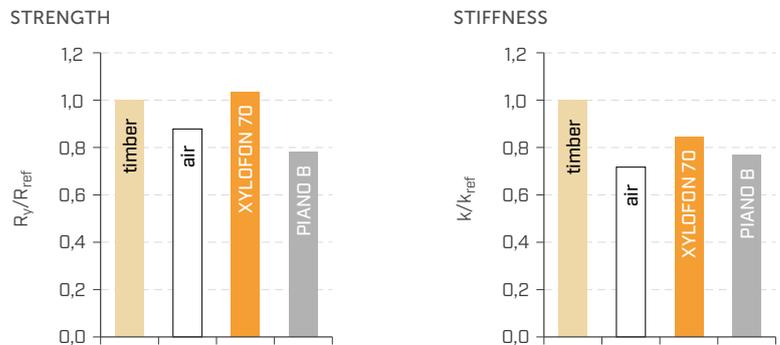

Graphical representation of experimental data from monotonic tests (left) and cyclic tests (right).

7 INTERPRETATION OF RESULTS

The comparative analysis focused mainly on strength and stiffness parameters. The values obtained in the various configurations were dimensioned with respect to the TIMBER case.

Monolithic, deformable **polyurethane and EPDM** profiles (represented by XYLOFON 70 in the graphs) do not significantly change the strength of the connection when the elastic modulus of the material changes compared to the timber-to-timber case.

With expanded and compressible profiles (represented by PIANO B in the graphs), on the other hand, the variation from the reference configuration is more significant.

parameter	influence on strength	influence on stiffness
 profile structure	medium-high $R_y \downarrow$ as compressibility increases ^(*)	medium
s [] profile thickness	significant $R_y \downarrow$ as thickness increases (for $s > 6$ mm)	significant
d [] connector diameter	medium $\Delta R_y \downarrow$ as the diameter increases	medium
 interface properties	significant $R_y \uparrow$ as the profile hardness decreases (shore)	low

(*) Directly proportional to the % of air contained in the material.

According to the analytical model, the use of **large thickness values ($s > 6$ mm)** leads to a progressive degradation of strength and stiffness regardless of the type of profile interposed.

Mechanical stiffness, on the other hand, shows a more or less marked degradation trend depending on the different parameters investigated and their interconnection.

In conclusion, the mechanical behaviour of the investigated connections under monotonic and cyclic loading conditions is not particularly influenced by the presence of the monolithic XYLOFON and PIANO acoustic profiles.

The strength values, as a first approximation, can, in the case of profiles with a thickness not exceeding 6 mm, always be traced back to the case of direct timber-to-timber connection, thus neglecting the presence of the acoustic profile.

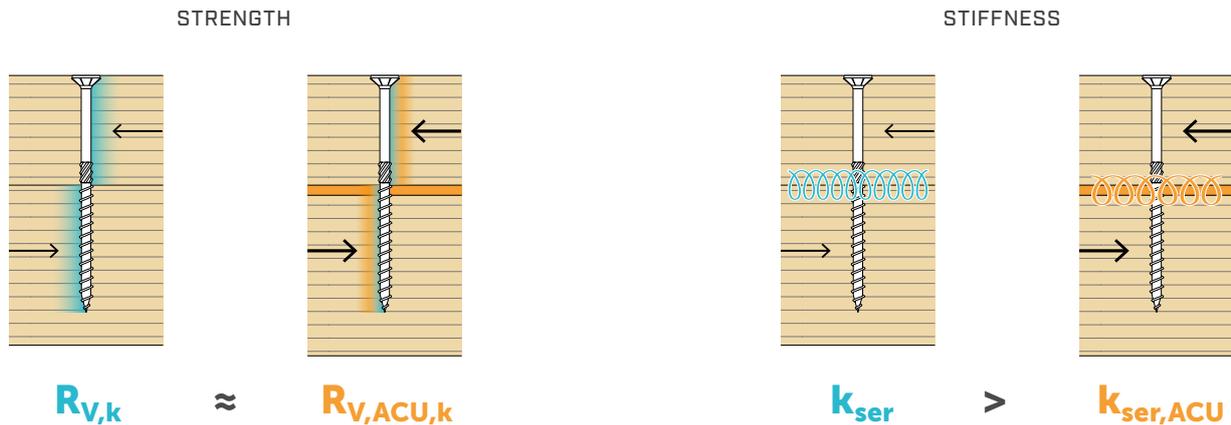

INTERACTION BETWEEN STRUCTURAL AND ACOUSTIC PERFORMANCE

How does a thin, resilient layer, designed for soundproofing, modify the mechanical behaviour of connections between timber elements?

Timber structures require appropriate soundproofing strategies in order to comply with increasingly stringent performance standards. Joints appear to be among the most critical aspects from both an acoustic and structural standpoint.

PARTIALLY THREADED SCREWS | HBS - HBS EVO - TBS - TBS EVO

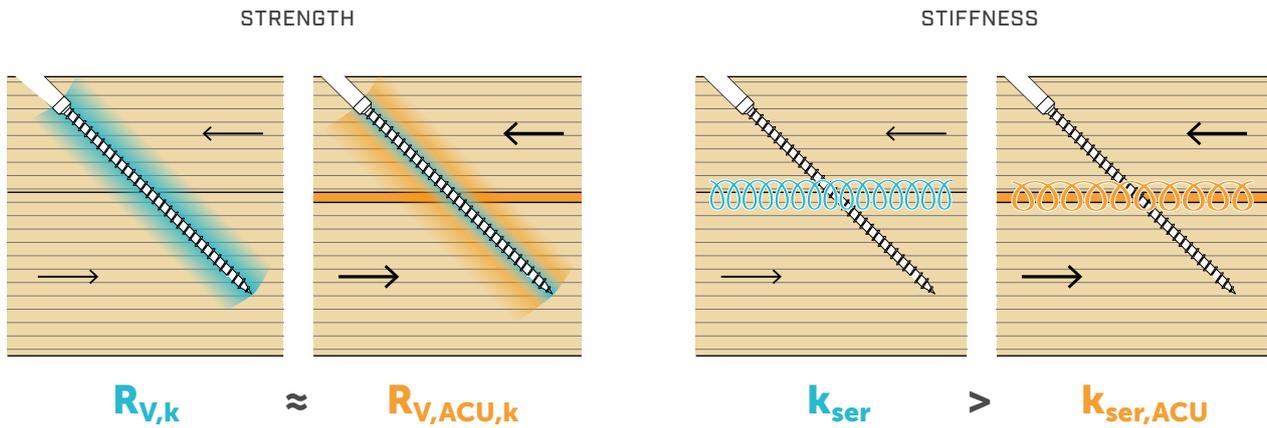

Monolithic, deformable polyurethane and EPDM profiles do not significantly change the **strength** of the connection when the elastic modulus of the material changes compared to the timber-to-timber case.

By contrast, the **stiffness** of the connection is significantly affected when a resilient profile is placed in between, which alters the system's behaviour under service conditions. Smaller diameters show greater deviations than larger diameters.

		STRENGTH

range	-	50-80%	40-75%	40-75%	25-40%	

FULLY THREADED SCREW | VGZ - VGZ EVO - VGS - VGS EVO

The profiles do not significantly affect the **strength** of the connection compared with the timber-to-timber case. The reduction is due to a smaller portion of the load-bearing thread within the timber element. By contrast, the **stiffness** of the connection is significantly affected when a resilient profile is placed in between, which alters the system's behaviour under service conditions.

NOTES and GENERAL PRINCIPLES on page 17.

STRUCTURAL VALUES

GENERAL PRINCIPLES

- Characteristic values comply with the EN 1995:2014 standard in accordance with ETA-11/0030.
- The characteristic values (CLT) are according to the national specifications ÖNORM EN 1995 - Annex K.
- For the mechanical resistance values and the geometry of the screws, reference was made to ETA-11/0030.
- Dimensioning and verification of the timber elements must be carried out separately.
- The screws must be positioned in accordance with the minimum distances.
- For the calculation process, a mass density of $\rho_k = 350 \text{ kg/m}^3$ has been considered for CLT elements and a mass density of $\rho_k = 385 \text{ kg/m}^3$ has been considered for timber elements.
- The reported deviation values with respect to the case without a profile in between ($\Delta\%$ mean) are to be understood as mean values of the tabulated cases.
- The axial thread withdrawal resistance in the narrow face is valid for minimum CLT thickness $t_{\text{CLT,min}} = 10 \cdot d_1$ and minimum screw pull-through depth $t_{\text{pen}} = 10 \cdot d_1$.
- For further information, please refer to the catalogue "Timber Screws and Deck Fastening" and/or the website www.rothoblaas.com.

NOTES | HBS AND TBS

- The design shear strength of the connector is obtained from the characteristic value as follows:

$$R_d = \frac{R_k \cdot k_{\text{mod}}}{\gamma_M}$$

The coefficients γ_M and k_{mod} should be taken according to the current regulations used for the calculation.

- The characteristic shear resistances are calculated for screws inserted without pre-drilling hole. In the case of screws inserted with pre-drilling hole, greater resistance values can be obtained.
- The characteristic shear strength is independent from the direction of the grain of the CLT panels outer layer.
- The characteristics shear resistance are calculated considering a minimum fixing length of $4 \cdot d_1$.
- The stiffness of connections with a resilient profile was evaluated by limiting the influence of the frictional component, in order to more accurately represent the actual behaviour under serviceability limit state conditions.

NOTES | VGZ AND VGS

- The design sliding strength of the joint is either the timber-side design strength ($R_{V,d}$) and the design strength on the steel side projected at 45° ($R_{\text{tens},45,d}$), whichever is lower:

$$R_{V,d} = \min \left\{ \begin{array}{l} \frac{R_{V,k} \cdot k_{\text{mod}}}{\gamma_M} \\ \frac{R_{\text{tens},45,k}}{\gamma_{M2}} \end{array} \right.$$

The coefficients γ_M and k_{mod} should be taken according to the current regulations used for the calculation.

- The characteristic strength on the steel side projected at 45° ($R_{\text{tens},45,k}$) is equal to:

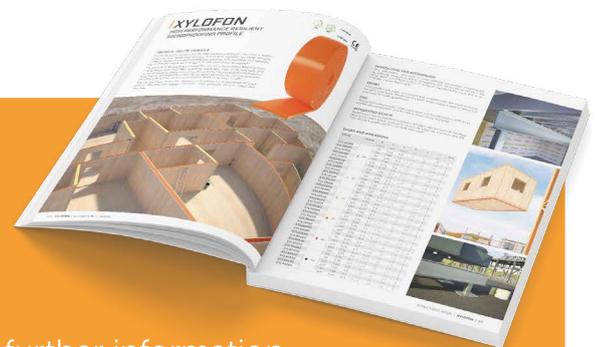

screw	d_1 [mm]	$R_{\text{tens},45,k}$ [kN]
VGZ	7	10,89
VGS/VGZ	9	17,96
VGS/VGZ	11	26,87
VGS	13	37,48

- The characteristic sliding strengths of the connectors inserted in the lateral face of the CLT panel were evaluated considering an angle ϵ of 45° between the grains and the connector, since it was not possible to define the thickness and orientation of the individual layers in advance.
- Connectors' instability must be verified separately.
- The stiffness of connections with the thread inserted into the narrow face was limited, in order to more accurately represent the actual behaviour under serviceability limit state conditions.
- The tabulated strength and stiffness values are not dependent on the type of resilient profile used.

For further information on **timber screws**, please consult the catalogue "TIMBER SCREWS AND DECK FASTENING"

Visit www.rothoblaas.com.

For further information on **resilient profiles**, please consult the catalogue "SOUNDPROOFING SOLUTIONS"

Visit www.rothoblaas.com.
